To push your local changes from the new branch to the remote repository, you can use the `git push` command. However, since this is a new branch, you'll need to set the upstream branch on the remote repository. Here's how you can do it:

```
git push --set-upstream origin new-branch
```

In this command:

- `git push` is used to push your commits to the remote repository.
- `--set-upstream` sets the upstream (tracking) reference for the current branch.
- `origin` is the default name given to your remote repository in Git.
- `new-branch` is the name of your branch.

After running this command, your changes in the `new-branch` will be pushed to the remote repository. Future pushes can be done with a simple `git push` while on this branch.
